

MINISTRY OF ENVIRONMENT
PROVINCE OF BRITISH COLUMBIA

THE ATTAINMENT OF AMBIENT
WATER QUALITY OBJECTIVES
IN 1989

Water Management Division

November, 1990

ACKNOWLEDGEMENTS

The regional staff of Environmental Protection (previously called Waste Management) carried out most of the monitoring, either directly or through contractors. Zenon Environmental Inc. analysed the samples. Information was also obtained from industries via Environmental Protection, from the Canada-B.C. Water Quality Monitoring Agreement, from regional offices of the Ministry of Health, from the federal departments of Environment and of Fisheries and Oceans, and from the Greater Vancouver Regional District.

1. SUMMARY

By the end of 1989, the Ministry had set water quality objectives in 24 bodies of water throughout the Province. These objectives represent safe conditions or levels of contaminants which will protect the most sensitive water use in each body of water. This report presents the results of monitoring done to check attainment of the objectives in 1989. The report is for the use of the managers of the water resource and will help guide them in carrying out more detailed assessments of the results. Familiarity with the background reports on water quality objectives for each basin is assumed.

The objectives to protect various water uses were set in water basins where water quality problems due to human activity were expected. The monitoring results indicate how well the quality of water in these basins is being safeguarded and thereby, indirectly, how well problems are being dealt with. Although the report does not describe the state of water quality in the Province as a whole, the information will be useful in state-of-the-environment-type reporting.

Results of monitoring to check water quality objectives are summarized in a series of tables. Overall, the objectives were met more than 90 percent of the time, a result similar to that found in 1988. Although this result falls short of an ideal 100 percent compliance, we must bear in mind that objectives are only set in problem areas. Variables for which objectives were sometimes exceeded included fecal coliforms, suspended solids, turbidity, nutrients, dissolved oxygen, pH, temperature, colour, cyanide, copper, iron, zinc, and chlorophenols. Objectives

for these variables were not, of course, exceeded in all the water basins tested.

Cases of objectives being exceeded should be assessed to determine the cause and the possible need for corrective action. Monitoring in future years will indicate whether the problem is persisting or the situation is improving.

The monitoring in 1989 was the third year for this program which began in 1987. In the future, new basins will be added and monitoring will be discontinued in areas where objectives are being met consistently. This will tend to change the overall results as we focus the program more on only those areas where there are many man-made water quality problems.

2. INTRODUCTION

In 1981, the Auditor General recommended that the Ministry develop a method of measuring its performance in safeguarding water quality. To fulfill this recommendation, the Ministry undertook to set water quality objectives for fresh and marine surface waters of British Columbia.

Water quality objectives are safe conditions or levels of contaminants which will protect the most sensitive water use of a specific body of water. They establish a reference against which the state of water quality at a specific site can be checked, as recommended by the Auditor General. They can also be used to prepare Waste Management Permits and to measure their effectiveness. They are thus a basic tool for use in maintaining a sustainable environment.

Work on water quality objectives began in 1982. By the beginning of 1990, objectives had been set in 24 separate bodies of water. In each water basin considered, some type of water quality problem could be expected due to human activity. Objectives have been set for lakes, rivers, creeks, and marine areas in all six Environmental Regions in the Province.

This report for 1989 is the fourth in a series of annual reports which began in 1986. In 1987, 1988, and 1989 funds were allocated for the ambient monitoring needed to check attainment of the objectives. As a result, a fairly accurate account of the attainment of objectives was obtained in 1987 and 1988 and is again given here for 1989.

The water basins in which water quality objectives are set are usually chosen because of perceived water quality

problems. Thus, results presented here indicate conditions in likely problem areas, but do not reflect the state of water quality in the Province as a whole. This is because there are many bodies of water where water quality is relatively unaffected by man and likely to remain so for the foreseeable future. Nevertheless, reports of this type will provide some of the basic data on water quality needed for "state-of-the-environment reporting" now being considered for British Columbia.

3. METHOD OF PRESENTING AND INTERPRETING THE MONITORING DATA

3.1 REPORTS ON OBJECTIVES

By the end of 1989, the Ministry of Environment had completed 24 reports on water quality objectives for specific bodies of water. The complexity and size of the reports varied considerably, depending upon the body of water considered. These bodies of water were distributed among the Environment Regions as follows:

Vancouver Island	2
Skeena	4
Northern Interior	8
Southern Interior	4
Kootenay	2
Lower Mainland	4

Work is in progress on another 22 reports for different water basins. These reports are now at various stages of completion.

3.2 TABLES OF RESULTS

Data collected in 1989 to check objectives are summarized in Tables 2 to 23, with a separate table for each water basin (the objectives for the 24th basin, namely tributaries to the lower Fraser River along the north shore, were not checked in 1989 because the report was finalized too late in the year).

Each table lists all the objectives that have been set, as they appear in the final reports on objectives. A few of the objectives have been updated to reflect new water quality criteria and procedures. For example, we are now using chlorophyll-a instead of periphyton biomass, and

total ammonia-N instead of un-ionized ammonia-N. The 90th percentile of 400 MPN/ 100 mL for fecal coliforms in bathing waters is used in cases when high fecal coliform values were recorded. The tables summarize the measurements made to check the objectives. These include sites, sampling dates, number of samples taken, and the values obtained. The sites and tributaries are listed in the tables in an upstream to downstream sequence, starting with the upstream site or tributary. Finally, a concluding statement about the results is given.

The conclusion states whether the objective was met or not met. The result is reported as indefinite if there are insufficient data to check the objective, or the data are suspect, or the minimum detectable concentration is too high. If no data were collected, the objective is reported as not checked. We consider these tables to be the most important part of this report since they demonstrate, in a factual way, how well objectives were met in 1989.

3.3 TEXT

The text in this report first gives a provincial overview of the results. We then describe briefly, by Region, the tabulated data for each body of water, mentioning the highlights and drawing some general conclusions. Qualifying statements such as: "The objectives were nearly met, slightly exceeded or probably met" are avoided as being too speculative without the support of further evidence to explain them. Thus, objectives exceeded by a wide margin are categorized equally with apparent borderline cases. While a more detailed interpretation is desirable, the work required to document the significance of results in more detail is beyond the scope of this report.

There is also no attempt to explain what may have caused the results or to comment on the effect of objectives not being met. Such assessments would entail consideration of flows, discharges, whether objectives are long term or short term, the degree to which objectives are exceeded, and many other factors. Assessments of this type are presently carried out by Regional Environmental Protection (previously Waste Management) on an ongoing basis.

The report is written to guide those involved in managing water quality by allowing them to focus on areas of concern where further assessment or inspection may be needed. Since monitoring to check water quality objectives covers only a short time span, usually at most 30 days, we believe that any instance when objectives were not met, however close the result, could be significant and is worth a more detailed look. Further study could show that certain objectives were exceeded due to natural phenomena. On the other hand it could reveal the need for corrective action if the cause of the problem was man-made.

3.4 FIGURES

The 24 water basins where objectives have been set are shown on a location map in Figure 1. The water basins (excluding the lower Fraser River tributaries) are also detailed in separate maps, Figures 2 to 23, on which sampling locations referred to in the tables are shown. Each figure number corresponds to the table of the same number.

4. PROVINCIAL OVERVIEW OF RESULTS

4.1 PRESENTATION OF RESULTS

In the tables summarizing the monitoring data, there are four kinds of concluding statements. These are: objective met, objective not met, objective not checked, and indefinite result.

To get an overview of performance for the Province, the number of occurrences for which objectives were met, not met, not checked, or were indefinite are totalled for each water basin from the summary tables. In compiling these totals, we counted each instance of a maximum (or minimum) objective being met or not met, as well as all average and percentile values.

The results of this compilation are shown in Table 1. The sum of occurrences for each kind of conclusion is given by Region and then totalled for the whole Province. The occurrences are also expressed as a percent of the total of all occurrences, both by Region and for the Province as a whole.

4.2 DISCUSSION OF RESULTS

Although the results apply to specific occurrences, we have assumed in this analysis that they are representative of the whole year. This simplification is justified, in part, by the fact that data were usually collected during worst case conditions.

Table 1 shows that the objectives were met 86% of the time in the Province as a whole. This result varied according to Region over a fairly small range, from 73% to

92%. Objectives were not met from between 3% to 10% of the time, with an overall average of 8%.

The occurrences of objectives not being checked and of indefinite results averaged 2.5% and 3.5%, respectively. If we subtract these relatively minor instances of no result from the total, then the percent of time that objectives were met and not met becomes 92% and 8%, respectively.

We can therefore state that in the Province as a whole the objectives were met over 90% of the time in 1989. This is an approximate statement since the frequency at which objectives are tested can vary among Regions and thus influence this value. For example, in the Middle Quinsam Lake basin of the Vancouver Island Region most of the objectives were not checked because there was no need to do so. This was because the coal mine that could affect the water quality of Middle Quinsam Lake was operating below 5% capacity in 1989.

The overall result for 1989 was virtually the same as for 1988, with only a marginal increase in cases of objectives not being met. As the monitoring program is repeated in future years the general picture could change. New basins will be added and there will be a tendency to cease monitoring in areas where objectives are being met consistently by a wide margin. As a first priority, we will concentrate on areas where man-made water quality problems occur. The goal, of course, is for water quality objectives to be met 100% of the time in such areas. It will be important to see how close we can get to this ideal situation in the future.

5. VANCOUVER ISLAND REGION

5.1 COWICHAN-KOKSILAH RIVERS

Data and site locations are presented in Table 2 and Figure 2, respectively.

The Cowichan River is the most important river on Vancouver Island for recreational and commercial fisheries. The Koksilah River is a major tributary of the Cowichan River near its mouth.

The objectives for microbiological indicators (fecal coliforms, *E. coli*, and enterococci) were generally not met in either river. These objectives are fairly restrictive since they were set to protect drinking-water use after disinfection only. The less restrictive objectives to protect recreation were met. The sources of possible bacteriological contamination need to be established.

Dissolved oxygen levels, measured in late summer and fall, were sometimes below the objective levels in both rivers. Although the levels were still high enough so as to not be an immediate threat to fish, we need to ascertain their cause.

The objectives for turbidity, suspended solids, ammonia, copper, lead, and zinc were met throughout both rivers. Objectives for chlorophyll-a and total chlorine residual were not checked in the Cowichan River.

5.2 MIDDLE QUINSAM LAKE

Data and site locations are presented in Table 3 and Figure 3, respectively.

Middle Quinsam Lake drains via the Quinsam River into the Campbell River near its estuary. The Middle Quinsam Lake sub-basin is a valuable habitat for trout and salmon and could be impacted by an open-pit coal mine now being developed in the area.

Not all the objectives needed to be checked because no effects on water quality were expected from the mine which operated at less than 50% capacity in 1989.

None of the objectives tested were exceeded. Objectives met included turbidity, suspended solids, ammonia, nitrate, pH, aluminum, arsenic, copper, iron, lead, manganese, and zinc. The results for cadmium, cobalt, and nickel were indefinite because detection limits were too high.

6. SKEENA REGION

6.1 BULKLEY RIVER

Data and site locations are presented in Table 4 and Figure 4, respectively.

The Bulkley River is a major tributary to the Skeena River. It is an important river for fisheries and has some drinking water use.

The objective for fecal coliforms was met where measured except just upstream from Houston. All other water quality objectives were met. This is the same result as obtained in 1988. Both show an improvement over 1987 when the objectives for chlorophyll-a as well as for fecal coliforms were exceeded.

The Morice River objectives were not checked since the river will not now be affected by Kemano completion.

6.2 KATHLYN, SEYMOUR, ROUND, AND TYHEE LAKES

Data and site locations are presented in Table 5 and Figure 5, respectively.

These four small lakes, in the Smithers area, are used for recreation, domestic water supply, and irrigation.

The fecal coliform objectives were generally met at domestic water intakes and beaches in all four lakes, except at an intake in Kathlyn Lake and one in Seymour Lake. These results suggest a minor deterioration since 1988.

The objectives for turbidity were exceeded at times in all four lakes. The objective for colour was met in Kathlyn and Tyhee lakes but exceeded in Seymour Lake and at times in Round Lake.

The total phosphorus objective could not be checked because spring overturn sampling was missed. The objectives for phosphorus are long-term since the lakes have a history of eutrophication.

6.3 LOWER KITIMAT RIVER AND ARM

Data and site locations are presented in Table 6 and Figure 6, respectively.

The river and arm are a migration route for salmonids, and the water is used for recreation and for industrial and municipal supplies. A kraft pulp mill and an aluminum smelter are located in the water basin.

The objectives for fecal coliform to protect recreation were met in Kitimat Harbour and Kitimat Arm. The stricter fecal coliform objectives to protect shellfish harvesting were met at certain sites in Kitimat Arm, although these sites are presently closed to shellfish harvesting.

The objective for suspended solids was exceeded at times in the Kitimat River and the Harbour, but met in the Arm. The objective for turbidity was met throughout.

The objective for average nitrite-nitrogen was not met in the Kitimat River, even upstream from all discharges, and the maximum objective was not met on occasion. The same situation was encountered in 1988.

There were some instances of objectives being exceeded for total copper and total iron in Kitimat Harbour and Arm, but objectives for other metals were generally met, including those for total aluminum, total cadmium, and total lead. Similar results were reported in 1988. For total aluminum, levels below the minimum detection limit used (0.5 mg/L) were considered to meet the objective.

Objectives for toxic contaminants such as cyanide, fluoride, and ammonia-nitrogen were met generally at all sites tested. Exceptions occurred in the harbour where levels of cyanide and fluoride exceeded the objectives on a few occasions. In the case of cyanide, our criteria document recommends that measurements below the current detection limit of 0.005 mg/L be considered acceptable.

The objective for pulp mill toxicity has yet to be checked in the Kitimat River.

6.4 LAKELSE LAKE

Data and site locations are presented in Table 7 and Figure 7, respectively.

Lakelse Lake drains into the Skeena River and is important for salmon spawning and rearing and for recreation. It is also used as a domestic water supply.

The objective for fecal coliforms was met at all water intakes tested. The same result was obtained in 1988.

All other objectives checked were met, as they had been in 1988 and 1987. These included objectives for turbidity, total phosphorus, and chlorophyll-a.

A measurement to check the dissolved oxygen objective was made for the first time and showed this objective was met.

7. NORTHERN INTERIOR REGION

7.1 CHARLIE LAKE

Data and site locations are presented in Table 8 and Figure 8, respectively.

Charlie Lake is used as a drinking water supply and for recreation.

At the bathing beaches, the geometric mean fecal coliform objective was met and the 90th percentile objective was usually met. There were no beach closures, an improvement over 1988. In the body of the lake, at the Fort St. John intake and Scurry intake, the more stringent fecal coliform objective to protect drinking water was not met. This represents a deterioration over 1988 and 1987 when the objective was met.

The total phosphorus objective was generally not met, except for at times in the centre and the North Arm of the lake. These results indicate that the lake continues to be in a eutrophic state.

7.2 BULLMOOSE CREEK

Data and site locations are presented in Table 9 and Figure 9, respectively.

Bullmoose Creek and its branches (West and South Bullmoose Creek) are adjacent to an open pit coal mine and contain important recreational fish habitat.

The objectives for turbidity and suspended solids were exceeded on occasion downstream from the sedimentation ponds. The problem occurred in May or June, presumably

during the freshet period. The objective for chlorophyll-a, checked in the fall, was often exceeded.

Objectives that were met included fecal coliforms, ammonia-nitrogen, nitrite-nitrogen, nitrite plus nitrate nitrogen, and pH. The dissolved oxygen objective was not checked in 1989.

The substrate sedimentation objective has yet to be checked in this basin.

7.3 NECHAKO RIVER

Data and site locations are presented in Table 10 and Figure 10, respectively.

The Nechako River, a major tributary to the Fraser River at Prince George, has its flow controlled for power generation. The river is an important route for migrating salmon.

The fecal coliform objective was met in the Stuart River, a tributary to the Nechako from the north side, and in the Necoslie River which is a tributary to the Stuart. In the Nechako River, where the objective is less stringent, the objective was met only immediately upstream from Vanderhoof and exceeded elsewhere. The objective was met in the Chilako River, a tributary to the Nechako from the southside, where it was measured for the first time.

Other objectives which were met in the Nechako, Stuart, and Chilako rivers, as applicable, included ammonia-nitrogen, nitrite-nitrogen, dissolved oxygen, and pH. The chlorophyll-a objective was not checked in any of the rivers in 1989.

The temperature objective at a site 8 km downstream from Cheslatta Falls was met during the winter months, from January to nearly the end of June and after mid-September. However, during the summer months the objective was frequently exceeded. A similar result was obtained in 1988 and 1987. A cold water release structure planned for the Kenney Dam will presumably correct the problem.

The objective for total gas pressure was checked for the first time in the Nechako River and was met throughout.

7.4 PINE RIVER

Data and site locations are presented in Table 11 and Figure 11, respectively.

The Pine River, a tributary to the Peace River, supplies water to Chetwynd and supports significant sportfish populations.

All objectives checked were met. These included objectives for fecal coliforms, turbidity, suspended solids, ammonia-nitrogen, nitrite-nitrogen, chlorophyll-a, and dissolved oxygen.

A thermal-mechanical pulp mill is being built near the Pine River, downstream from the Murray River. Although the plan is for zero-discharge, water quality objectives should be updated in the future.

7.5 POUCE COUPE RIVER

Data and site locations are presented in Table 12 and Figure 12, respectively.

The Pouce Coupe River and its tributary, Dawson Creek, run into the Peace River inside the Alberta Border. The waters are affected mainly by municipal discharges.

The fecal coliform objective for the Pouce Coupe River was met, as it was in 1988.

Turbidity and suspended solids objectives were met in the Pouce Coupe River but were often exceeded in Dawson Creek.

The objectives for nitrite-nitrogen were met in both streams. Those for ammonia-nitrogen were sometimes exceeded in both streams, especially in Dawson Creek.

The chlorophyll-a objective was not met in the Pouce Coupe, downstream from the municipal discharge, a result similar to 1988 and 1987, but was not checked in Dawson Creek. The dissolved oxygen objective was not checked in either stream in 1989.

7.6 PEACE RIVER

Data and site locations are presented in Table 13 and Figure 13, respectively.

Objectives were set for the Peace River between the Bennett Dam and the B.C.-Alberta Border. The water is important for aquatic life and irrigation and can be affected by municipal discharges, an oil and gas refinery and a pulp mill built in 1988, after the objectives were set. The objectives were first checked in 1988.

The following objectives were met in both the Peace River and the Beatton River (a tributary), as applicable: fecal coliforms - except immediately downstream from the

pulp mill, fluoride, cyanide, ammonia-nitrogen, nitrite-nitrogen, dissolved oxygen, and pH. The temperature objective was met throughout except for one instance downstream from the pulpmill. The result for sulfide was indefinite because the detection limit was too high.

Turbidity and suspended solids objectives were generally met in the Peace River and also in the Beatton River except downstream from the Fort St. John discharges and from the pulpmill. The objective for chlorophyll-a was not checked in 1989 although it was generally not met in the Peace River in 1988.

Regarding heavy metals, the objectives for total lead and total nickel were met in the Peace River. The objectives for total copper were exceeded immediately downstream from the refinery. The objective for total chromium was exceeded immediately downstream from Fort St. John. The objective for total zinc was met except on one occasion downstream from Fort St. John.

Regarding organics, the results for chlorophenols were strictly indefinite but the objective was considered to be met because of the low detection limits used. The objective for phenols was also met, except immediately downstream from Petro-Canada. The objective for 2,4-D was not checked although it was met at all sites in 1988.

The objective for dissolved gas was checked for the first time and was met throughout the Peace River.

7.7 WILLIAMS LAKE

Data and site locations are presented in Table 14 and Figure 14, respectively.

Williams Lake is important for drinking water, recreation, and aquatic life. The water quality is affected by nutrients from traditional farming practices in the San Jose drainage, the main inlet to the lake.

The objective for fecal coliform to protect bathing beaches was met. The fecal coliform objective to protect drinking water was also met.

The total phosphorus and chlorophyll-a objectives were not met, indicating the continued eutrophic state of the lake.

Objectives for turbidity and dissolved oxygen were not met although water clarity was met on the single occasion it was measured. Such results can be expected in a eutrophic lake until some form of lake restoration is carried out.

7.8 UPPER FINLAY RIVER

This area was the site of a gold and silver mine and mill, now closed. Objectives applied to Jock and Galen creeks which eventually flow into the Upper Finlay River.

The objectives were checked in 1987. Since the area is remote and the operation is closed, no further monitoring was carried out in 1988 and 1989. The mill was reactivated in 1989 and therefore future monitoring may be needed.

8. SOUTHERN INTERIOR REGION

8.1 BONAPARTE RIVER

Data and site locations are presented in Table 15 and Figure 15, respectively.

The Bonaparte River is a tributary to the Thompson River. It is an important trout habitat and is affected by cattle farming and municipal discharges. Its main tributaries are Clinton Creek and Loon Creek.

The fecal coliform objective was met in the upper reaches of the Bonaparte River. In Clinton Creek, the objective was met, a reverse of the 1988 result. The objective was also met near the mouth of the Bonaparte River but exceeded downstream from the Cache Creek sewage treatment plant. The fecal coliform objective was not met in Loon Creek, also a reverse of the 1988 result. The more restrictive objective for Loon Lake was met, however.

The objectives for suspended solids and turbidity were frequently not met during freshet in the Bonaparte River, although they were met in Clinton Creek and in Loon Creek. Since suspended material entered the streams from diffuse sources, only one upstream control site was used to check these objectives.

An objective for dissolved solids, applicable only to Clinton Creek, was not checked in 1989 although the objective was exceeded in 1988.

The objectives for ammonia-nitrogen were met in the Bonaparte River and in Clinton and Loon creeks. The same result was obtained for nitritenitrogen.

The chlorophyll-a objective was not met in the Bonaparte River. A less stringent objective for Clinton Creek was not checked in 1989.

The dissolved oxygen objective was not checked in the Bonaparte River and was not met in the summer in Loon Lake. The pH objective was met in the Bonaparte River and in Loon Creek, but was occasionally exceeded in Clinton Creek, a similar result to 1988. Clinton Creek may have a naturally high pH level.

8.2 OKANAGAN VALLEY LAKES

Data and site locations are presented in Table 16 and Figure 16, respectively.

Objectives have only been set so far for phosphorus, which is the main factor controlling the trophic state of the lakes. The lakes are highly valued for recreation, fisheries, and as a source of drinking and irrigation water.

The total phosphorus objective was met in Kalamalka Lake and in the main body of Okanagan Lake. The results for Armstrong Arm and Vernon Arm were indefinite because sampling was not done at spring overturn. The objective has been exceeded historically in the arms. The objective was not met in Wood Lake, Skaha Lake, or Osoyoos Lake.

These results were similar to those obtained in 1987 and 1988.

8.3 SIMILKAMEEN RIVER

Data and site locations are presented in Table 17 and Figure 17, respectively.

The Similkameen River is important for fisheries, drinking water, and irrigation. Water quality can be affected by mining and municipal discharges. The water quality objectives were updated in 1990 because of an increase in mining activity.

The fecal coliform objective, set to protect the water for drinking after disinfection only, was exceeded at times in the Similkameen River but was met in Allison Creek, a tributary. In the main lakes draining to the Similkameen River (Allison, Osprey, and Missezula lakes), the results were indefinite because of too few samples.

Objectives for ammonia-nitrogen and pH were met in the Similkameen River. The pH objective was also met in Wolfe Creek, a tributary adjacent to a copper mine.

The total phosphorus objective was exceeded in Missezula Lake, measured at the wrong time in Allison Lake, and checked incompletely in Osprey Lake.

Regarding heavy metals, the objectives for dissolved copper and dissolved zinc were met in the Similkameen River and in Wolfe Creek. Other objectives measured in Wolfe Creek were dissolved manganese and iron, which were met and dissolved molybdenum for which the average objective was exceeded downstream from the mine. These results were similar to those of 1988.

8.4 CAHILL CREEK

Data and site locations are presented in Table 18 and Figure 18, respectively.

Cahill Creek, its tributaries (Nickel Plate Mine Creek and Sunset Creek), and a parallel stream (Red Top Gulch Creek) enter the Similkameen River near Hedley. This watershed is the site of a gold mine and mill which started operation in August, 1987.

Many of the objectives were met in 1989, as they had been in 1988 and 1987. They included objectives for suspended solids, turbidity, strong-acid dissociable cyanide and thiocyanate, arsenic, ammonia-nitrogen, nitrite-nitrogen, and nitrate-nitrogen. A major exception was the objective for weak-acid dissociable cyanide, which was not met in Cahill Creek at its mouth, as was the case in 1988. The cyanate objective was also exceeded in 1989, in Red Top Gulch Creek. The objectives for dissolved solids and pH were generally met, except on occasion in Nickel Plate Mine Creek.

Among the metals the following objectives were met: total aluminum, dissolved iron, total lead, total molybdenum, total cadmium, total mercury, and total selenium. The objectives for total copper and total zinc were met, except on occasion in Nickel Plate Mine Creek. The objectives for total mercury in fish and total silver in water were not checked.

9. KOOTENAY REGION

9.1 COLUMBIA AND WINDERMERE LAKES

Data and site locations are presented in Table 19 and Figure 19, respectively.

The two lakes are important to fisheries, recreation, and drinking water.

All objectives set for the lakes were met, except turbidity in Columbia Lake which was not checked. Objectives that were met included those for fecal coliforms at water intakes and bathing beaches, turbidity in Windermere Lake, and total phosphorus in both lakes. The results for total phosphorus were similar to those obtained in 1988.

9.2 TOBY CREEK AND UPPER COLUMBIA RIVER

Data and site locations are presented in Table 20 and Figure 20, respectively.

Toby Creek enters the upper Columbia River just downstream from Windermere Lake. Both streams are important for aquatic life and recreation and can be affected by domestic sewage discharges. Toby Creek can also receive drainage from an abandoned mine.

The fecal coliform objectives were generally exceeded in Toby Creek and in the Upper Columbia River upstream from Radium. At Edgewater, further downstream, the results were indefinite due to insufficient sampling. These results show a deterioration since 1988.

All other objectives, which apply to Toby Creek, were met where checked. These included objectives for turbidity, suspended solids, ammonia-nitrogen, nitrite-nitrogen, chlorophyll-a, dissolved copper, total lead, and total zinc. The objective for barium in Toby Creek was not checked and the result for cadmium was indefinite.

10. LOWER MAINLAND REGION

10.1 FRASER RIVER FROM HOPE TO KANAKA CREEK

Data and site locations are presented in Table 21 and Figure 21, respectively.

Objectives were set for the Fraser River, tributaries entering from the south, and all major water courses between the Fraser River and the International Border. The Fraser River is a major salmon migration route and the tributaries are important spawning areas. The river and many of the tributaries are also used for irrigation.

The fecal coliform objective was met in the Fraser River and in several tributaries including Hope Slough, Elk Creek, Luckakuck Creek, Atchelitz Creek, Chilliwack Creek, and the Salmon River. The objective was also met at Cultus Lake bathing beaches. The objective was exceeded in Bertrand Creek, downstream from the Aldergrove sewage lagoons. Fecal coliform objectives were not checked in Saar Creek, the Sumas River, the Chilliwack River, and at Cultus Lake water intakes.

The ammonia-nitrogen objectives were met in the Fraser River except, at times, immediately downstream from the Chilliwack sewage treatment plant. The objectives were met in all the tributaries checked.

The dissolved oxygen objective was met in the Fraser River at all sites tested. In the tributaries, the dissolved oxygen objective was not met at times in Hope Slough, Elk Creek, and Atchelitz Creek. The dissolved oxygen objective was met in Chilliwack Creek, Luckakuck Creek, Bertrand Creek, and the Salmon River.

The objective for pH was met in the Fraser River and in all the tributaries.

10.2 FRASER RIVER FROM KANAKA CREEK TO THE MOUTH

Data and site locations are presented in Table 22 and Figure 22, respectively.

The river and outer estuary are important for salmon migration and rearing. The water is used for irrigation and certain beaches are important for recreation. Water quality can be affected by major discharges of municipal and industrial effluents.

The fecal coliform objective was met in the Main Stem, the North Arm (except on one occasion off Sea Island), and the Middle Arm. In the Main Arm, it was not met at times downstream from the Annacis sewage treatment plant, downstream from the Lulu sewage treatment plant, and just downstream from Steveston. The objective was met at all points along Iona Beach and along Tsawwassen Beach. These results are similar to those of 1988.

The objective for ammonia-nitrogen was met in the Main Arm, the North Arm, and in the Middle Arm. It was not checked on Sturgeon Bank and Roberts Bank.

The dissolved oxygen objective was met in the Main Stem and in all the river arms except, at times, in certain sloughs. These included Gunderson, Deas, Ladner and MacDonald sloughs. The objective was not checked on the Banks and never has been in the past. Measuring dissolved oxygen in surface waters of the Banks should be an important priority for future monitoring.

The pH objective was met in the Main Stem, the Main Arm, the North Arm (except downstream from Belkin), and the Middle Arm.

The objectives for total copper, total lead, and total zinc were met in the North Arm and the Middle Arm. They were also met in the Main Arm except at the mouth where the maximum copper objective was exceeded on one occasion.

The results for chlorophenols in water were strictly indefinite but the objective was considered to be met in the Main Stem and in the Main Arm because of the low detection limits used. The results were indefinite in the North Arm where some positive measurements for pentachlorophenol were obtained. The objective for chlorophenol in sediment was met in the Main Stem but was exceeded throughout the Main Arm and North Arm.

The objective for PCBs in sediments was met in all points of the Main Stem, the Main Arm, and the North Arm.

The objectives for chlorophenols and PCBs in fish tissue were met in 1988 following extensive testing. No data were collected in 1989.

The objective for suspended solids was met in the North and Middle arms, except for one instance at the Oak Street Bridge.

10.3 BOUNDARY BAY

Data and site locations are presented in Table 23 and Figure 23, respectively.

Boundary Bay sustains a crab and herring fishery and is important for recreation. Its main tributaries, namely the

Little Campbell River, the Serpentine River, and the Nicomekl River, provide important habitat for trout and salmon and are used for irrigation. This is the second year that these objectives have been checked.

The fecal coliform objective to protect water for recreation was generally met at beaches in Boundary Bay except on some occasions. In these cases the maximum objective was exceeded at sites in White Rock on the westside and Centennial Beach on the eastside. In the tributary rivers, the fecal coliform objective to protect irrigation use was met in the main stem of the rivers but exceeded in some of their tributaries. These included Mahood, Latimer, and Hyland creeks, which are all tributaries to the Serpentine River.

The objectives for suspended solids and turbidity were exceeded a number of times in the three tributary rivers and in the creeks which flow into them. The high values occurred in the September to November period. Similar results were obtained in 1988. The objectives were not checked in Boundary Bay.

The objective for substrate sedimentation was checked for the first time in 1989. It was met in the Serpentine River, Latimer Creek, and Mahood Creek. The objective was exceeded near the mouths of the Little Campbell River, Murray Creek, and Hyland Creek.

The objectives for ammonia-nitrogen were met in all the tributaries. However, the objectives for nitrite-nitrogen were often exceeded. Similar results were obtained in 1988. The chlorophyll-a objective was met in Mahood and Hyland Creeks but was not checked elsewhere.

The dissolved oxygen objective was not met on several occasions in the three tributary rivers and in the creeks flowing into them. The dissolved oxygen objective was also not met on a few occasions in Boundary Bay. This situation suggests a deterioration over results reported in 1988.

The pH objective was exceeded at times in the Serpentine River and its tributaries but met elsewhere.

The objectives for total lead in the Nicomekl River were met.

Checking the objective for PCBs in water of the Serpentine River and its tributary creeks gave indefinite results because of the high detection limit used. The objective for PCBs in the sediments was met in all areas of Boundary Bay and in the Serpentine River and its tributaries. The objective for PCBs in fish from the Serpentine River and its tributaries was not checked.
